

String Challenge

Have the function `StringChallenge(str)` take the `str` parameter being passed and return a new string where every character, aside from the space character, is replaced with its corresponding decimal character code.

For example: if `str` is "dog" then your program should return the string 100111103

Explanation: d = 100, o = 111, g = 103

Examples:

Input: "hello world"

Output: 104101108108111 119111114108100

Input: "abc **"

Output: 979899 4242
